

Mastering Vector Data Structures and Algorithms in Python

Student Name:
Class:
Due Date:
ntroduction to Vector Data Structures and Algorithms
Essential Understanding:
 Definition of vectors and their importance in programming Basic vector operations, such as addition and scalar multiplication Introduction to NumPy and Matplotlib libraries
Complete these concept checks:
Define what a vector is and provide an example of its use in programming.
2. Write a Python program that creates a vector with 3 elements and prints its components.

Vector Basics and Operations

Vector Addition and Scalar Multiplication: Write a Python program that performs basic vector operations, such as addition and scalar multiplication. **Matrix Multiplication:** Use the NumPy library to perform matrix multiplication. **Vector Visualization:** Use the Matplotlib library to visualize a 2D vector.

Create a Python program that visualizes a 3D vector using Matplotlib.					

Algorithm Implementation and Real-World Applications

Choose ONE of these topics for detailed research:

Scientific Simulations: Write a Python program that simulates a real-world application of vec
such as a scientific simulation or engineering problem.

oo any combination:
se any combination:
mplement an advanced algorithm, such as calculating the eigenvalues and eigenvectors of matrix.
ilauix.

Assessment and Extension Activities

To assess your understanding of vector data structures and algorithms, complete the following tasks:

Create a Python program that calculates the magnitude and direction of a vector.
2. Write a Dython program that performs basic vector enerations, such as addition and scalar
Write a Python program that performs basic vector operations, such as addition and scalar multiplication.
Extension Activities:
Implement an advanced algorithm, such as calculating the eigenvalues and eigenvectors of a
matrix.
2. Create a Python program that simulates a real-world application of vectors, such as a game or
simulation.

Glossary and References

Glossary:

- Vector: A mathematical object with both magnitude and direction.
- Matrix: A rectangular array of numbers.
- NumPy: A library for the Python programming language, providing support for large, multidimensional arrays and matrices.

Vector Operations and Transformations

Vectors can be added, subtracted, and scaled using various operations. These operations are essential in linear algebra and are used extensively in computer graphics, physics, and engineering. The addition of two vectors results in a new vector that is the sum of the corresponding components of the original vectors. Similarly, the subtraction of two vectors results in a new vector that is the difference of the corresponding components of the original vectors.

Example: Vector Addition

Consider two vectors A = (2, 3) and B = (4, 5). The sum of these vectors is C = A + B = (2 + 4, 3 + 5) = (6, 8).

Task: Vector Operations

1.	Write a Python program that performs vector addition and subtraction.
L	

2.	Use the NumF	⊃y library to pe	erform vector sc	aling and norma	alization.	

Linear Independence and Span

Linear independence is a fundamental concept in linear algebra that describes a set of vectors that are not linearly dependent. A set of vectors is said to be linearly independent if none of the vectors in the set can be expressed as a linear combination of the other vectors. The span of a set of vectors is the set of all linear combinations of the vectors.

Case Study: Linear Independence

Consider three vectors A = (1, 0, 0), B = (0, 1, 0), and C = (0, 0, 1). These vectors are linearly independent because none of them can be expressed as a linear combination of the other two. The span of these vectors is the entire 3D space.

Practice Questions:

1.	Determine whether the vectors $A = (1, 2)$ and $B = (3, 4)$ are linearly independent.
2.	Find the span of the vectors A = (1, 0) and B = (0, 1).

2. Calculate the steady-state probability distribution of the Markov chain.

Page Rank Algorithm

The PageRank algorithm is a link analysis algorithm used by Google to rank web pages in their search engine results. The algorithm assigns a numerical weight to each web page, called the PageRank, which represents the probability that a random surfer will land on that page.

Example: Page Ra	ank Algorithm	
	n with three pages: A, B, and C. The PageRank algorithm ass and quality of links pointing to it.	igns a score to each page
Task: Page Rank Alg	gorithm	
1. Write a Python p	program that implements the PageRank algorithm.
